- Azure Data Factory – DEPLOYMENT only
- Two (three?) methods of ADF deployment
- How these methods work
- Differences
- npm module from Microsoft – now you can fully automate CI (build)
- #adftools – make your life easier!

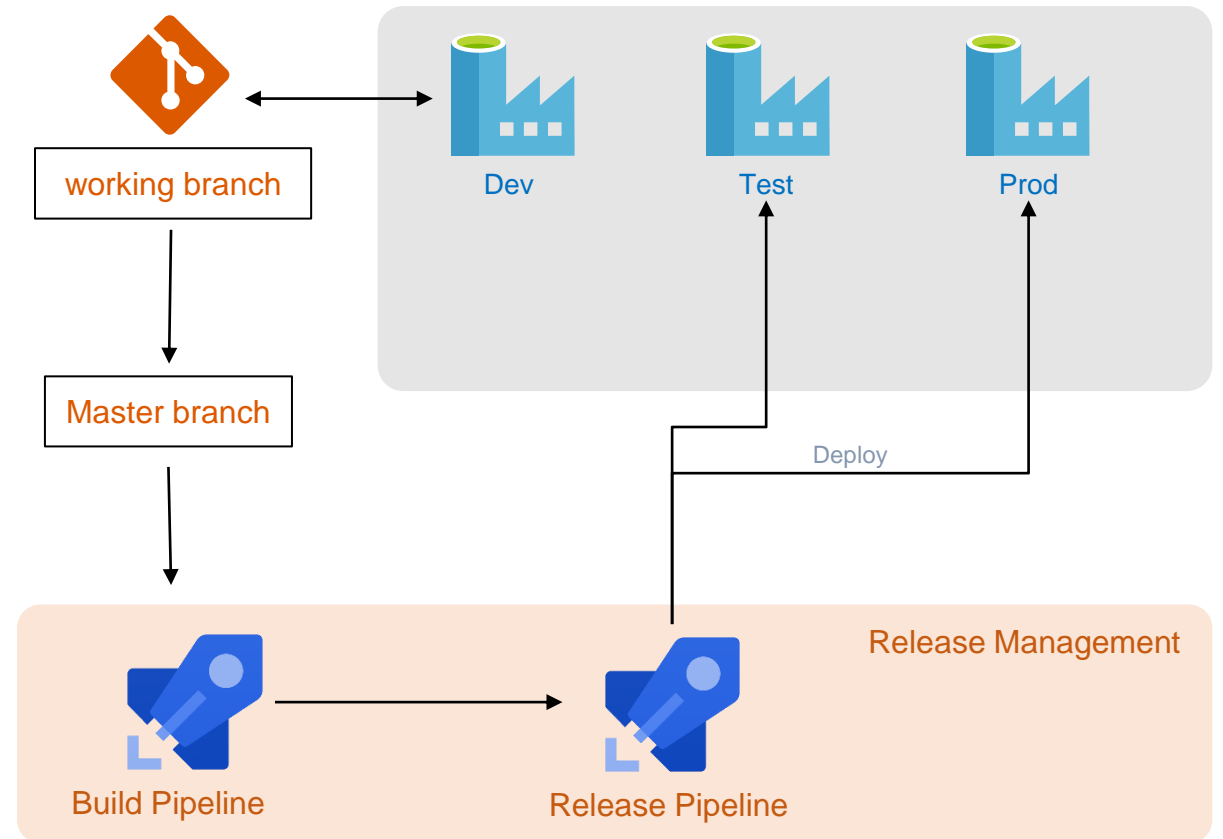

# ADF – Currently available methods of deployment

ARM Template from "adf\_publish" branch

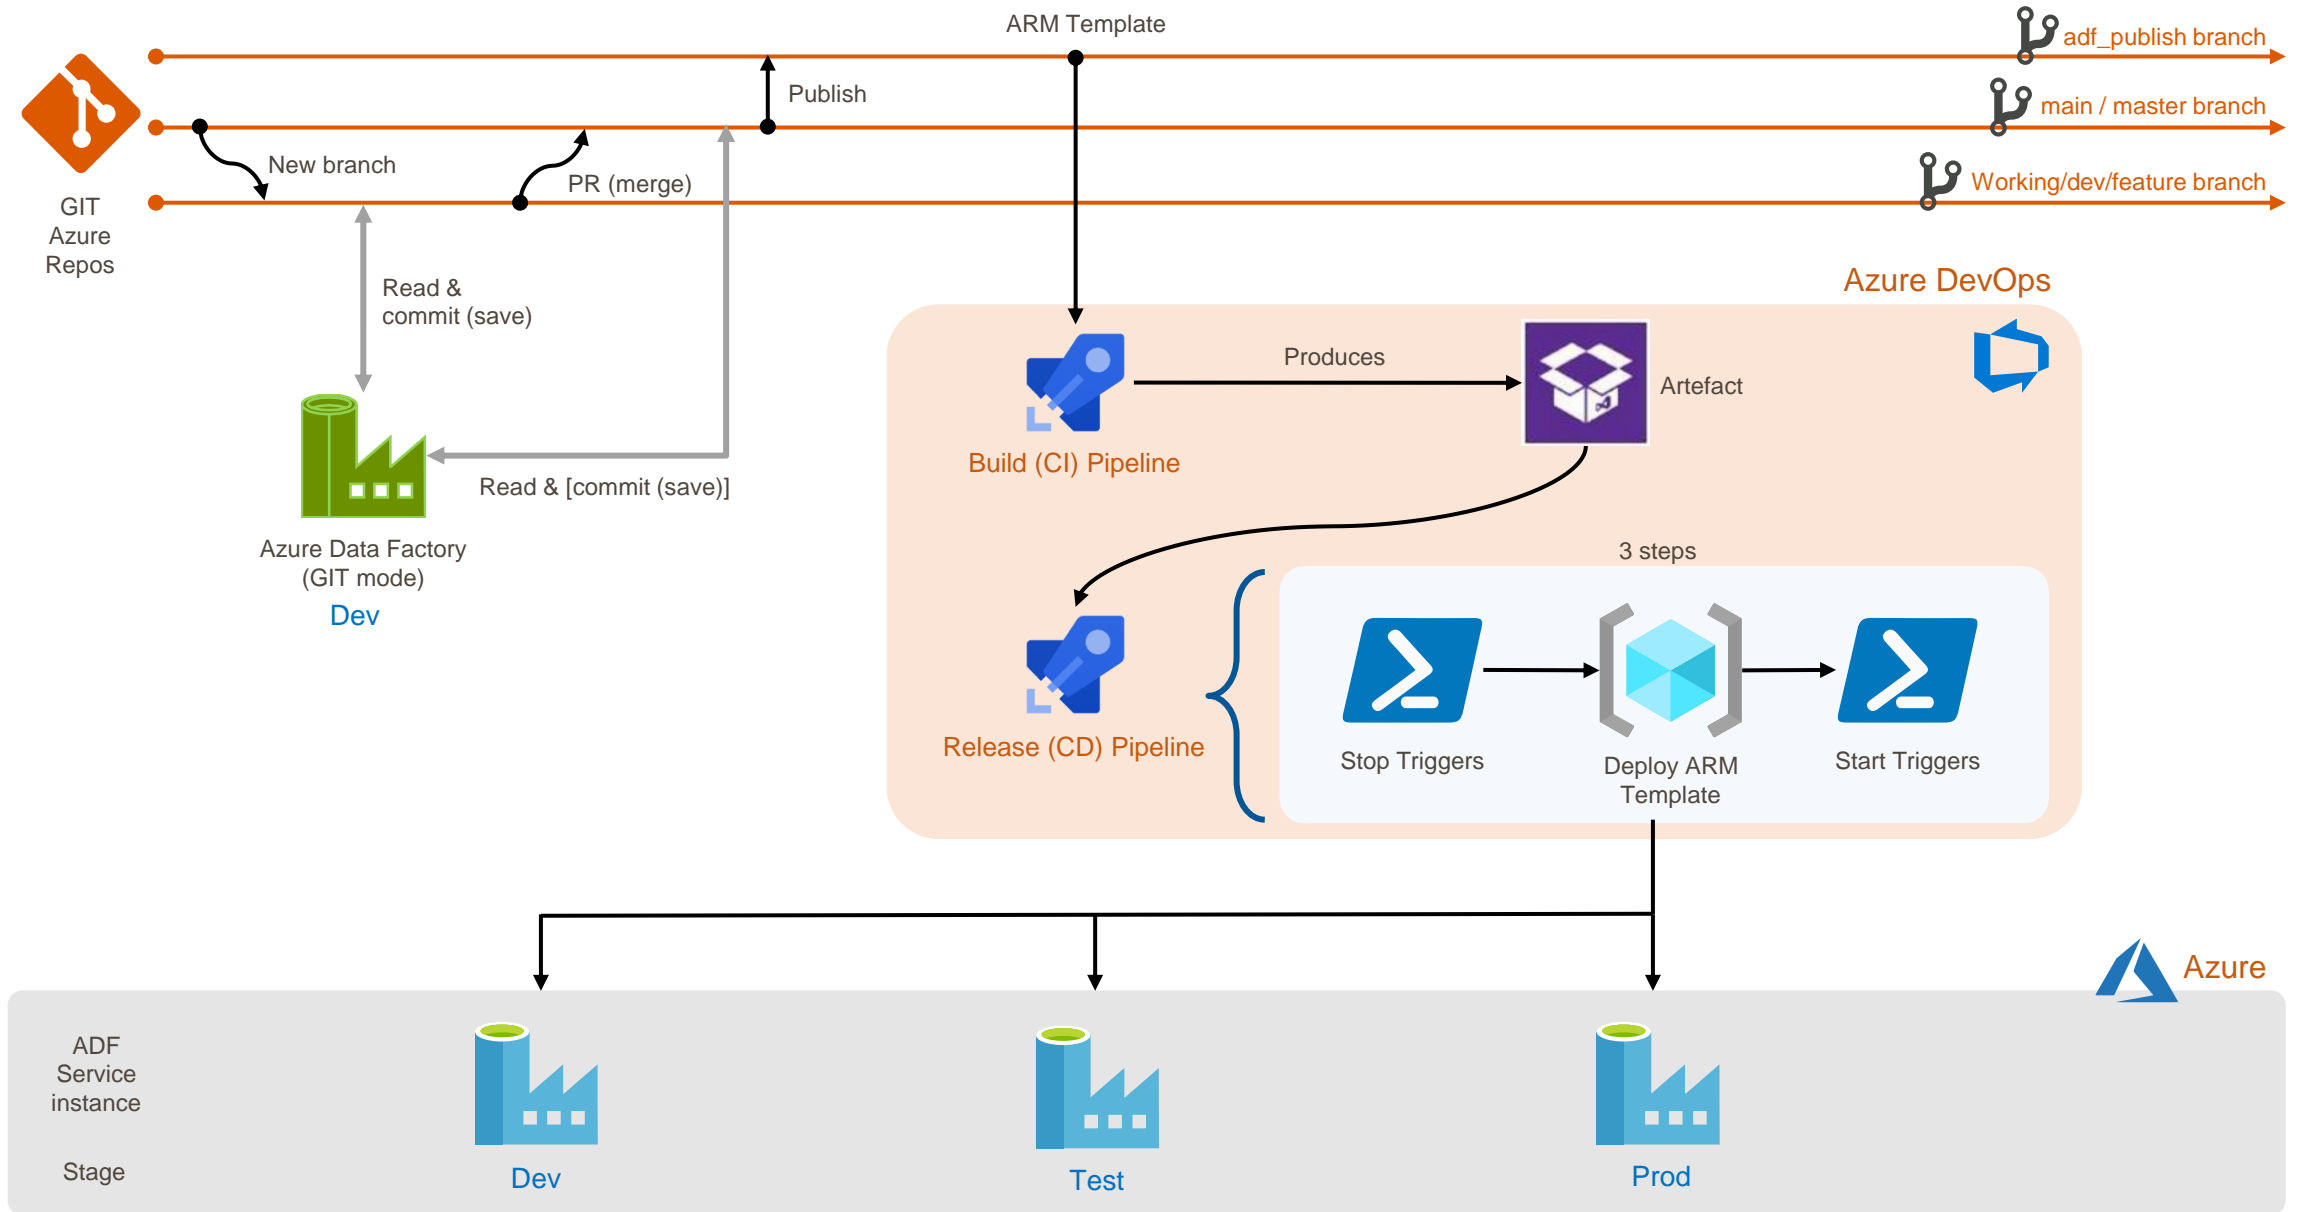

Rest-API/PowerShell script from code (JSON objects)

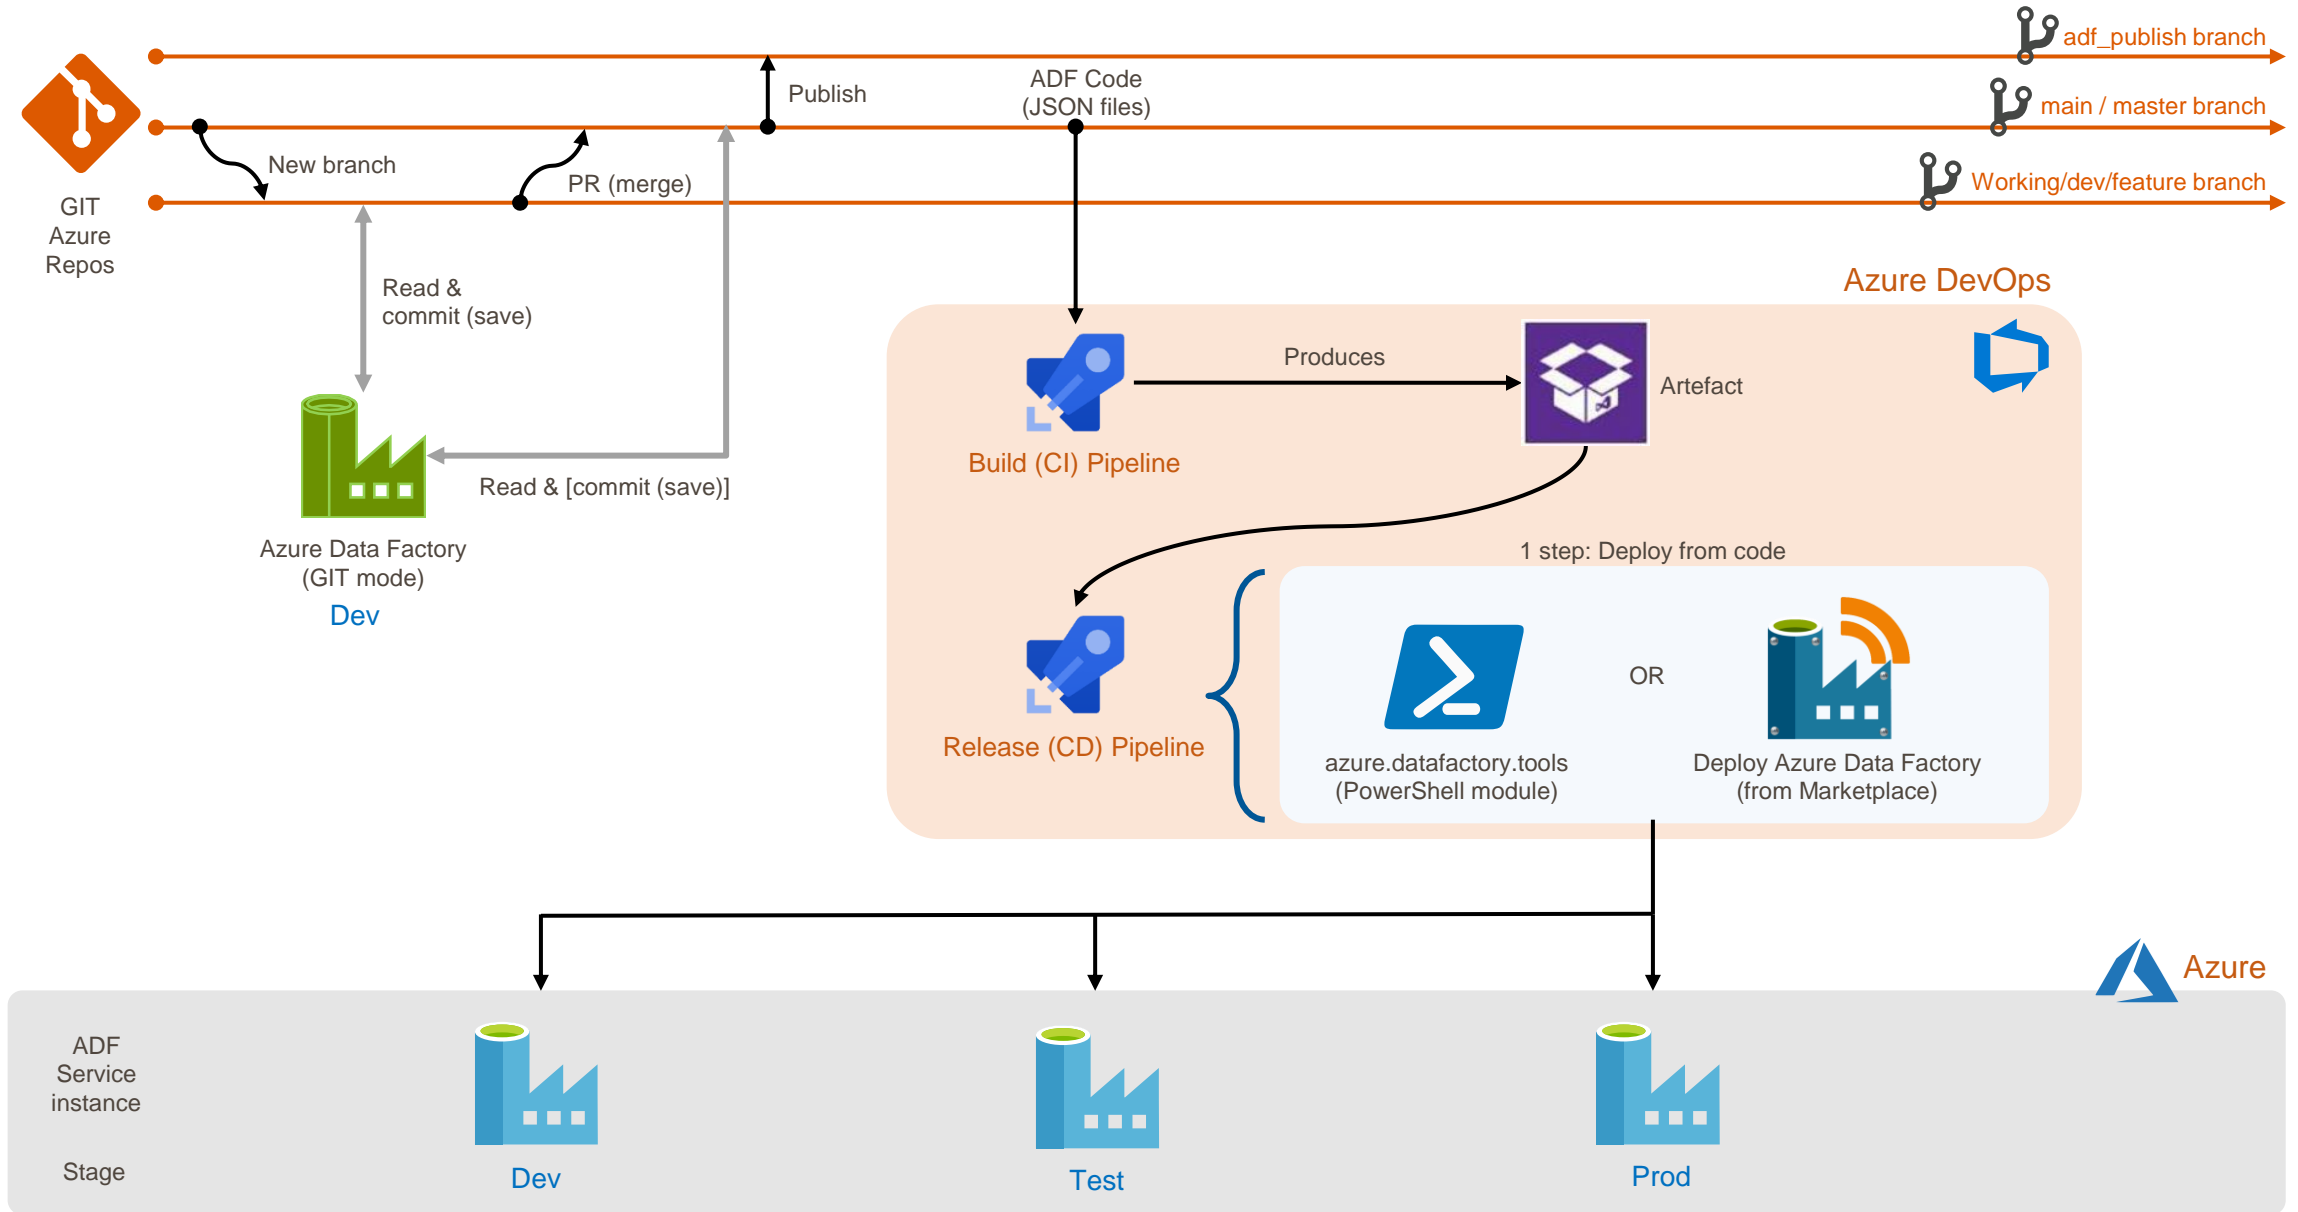

# Deployment (1): Microsoft's method (ARM Template)

# Deployment (2): Directly from code method

# Who use what?

**Kamil Nowinski**  
@NowinskiK

My dear [#sqlfamily](#) [#azurefamily](#) members. How do you deploy your [@AzDataFactory](#) from a code repo?  
[#devops](#) [#cicd](#)

# ADF – Currently available methods of deployment – pros & cons

## ARM Template from “adf\_publish” branch

- Faster
- Appears in „Deployments” for Resource Group
- Parametrize elements exposed within the ARM Template Parameter \*
- Full ADF (all artefacts) can be deploy only
- Restriction of 256 parameters
- Limitation to one publish branch only (adf\_publish)
- Manual “Publish” step

## Rest-API/PowerShell script from code (JSON objects)

- Slower
- Doesn't appear in „Deployments” for Resource Group
- Parameterize any artefact of the Data Factory
- Selectively deploy a subset of artefacts
- Eliminates an enforcement to use only one (adf\_publish) branch if company's branches policy is much complex

# ADF – ARM Template enhanced deployment method

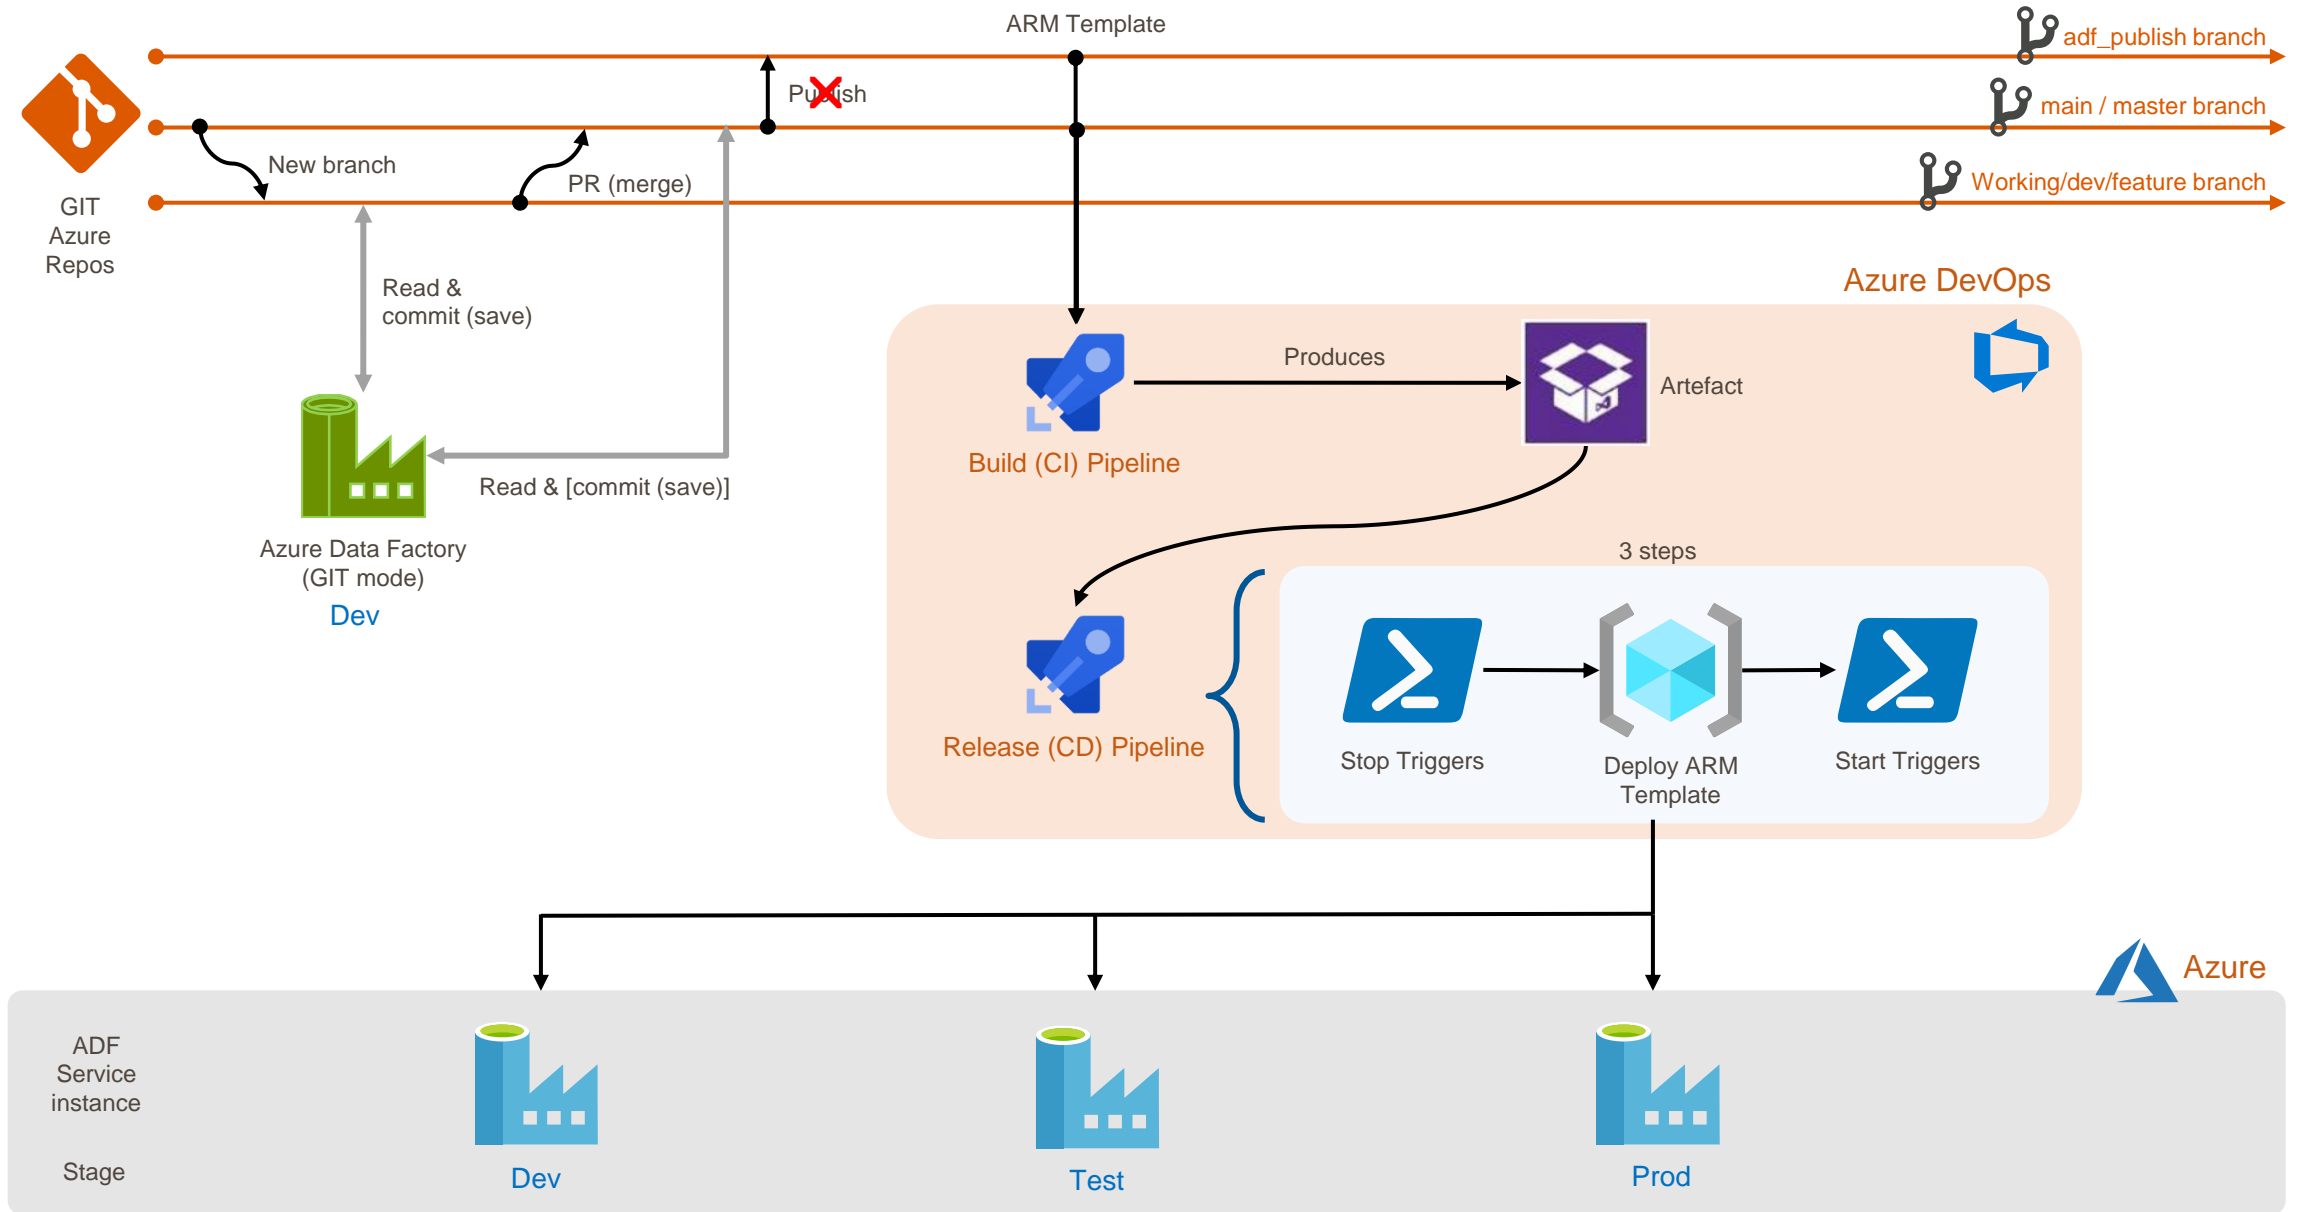

## ARM Template from “adf\_publish” branch

- Faster
- Appears in „Deployments” for Resource Group
- Parametrize elements exposed within the ARM Template Parameter \*
- Full ADF (all artefacts) can be deploy only
- Restriction of 256 parameters
- ~~• Limitation to one publish branch only (adf\_publish)~~
- ~~• Manual “Publish” step~~

## Rest-API/PowerShell script from code (JSON objects)

- Slower
- Doesn't appear in „Deployments” for Resource Group
- Parameterize any artefact of the Data Factory
- Selectively deploy a subset of artefacts
- Eliminates an enforcement to use only one (adf\_publish) branch if company's branches policy is much complex

# Deployment (1b): ARM Template exported by CI

# DEMO #1

# ARM Template deployment

# #adftools

Two tools:

PowerShell module (azure.datafactory.tools)

Azure DevOps extension (3 tasks)

<https://sqlplayer.net/adftools/>

# DEMO #2

# Deployment with PowerShell

# Azure DevOps: Custom Tasks

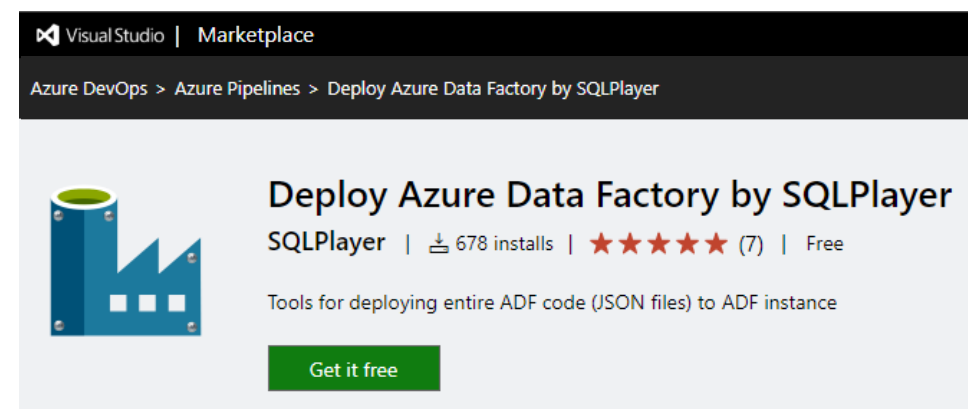

Key concept:

- Free & Open-Source
- One task for everything when it comes to the publishing of ADF
- Basically, it is another (UI) layer on top of „azure.datafactory.tools“ module
- Public Release (GA) since 23/12/2020
- Extension contains 3 tasks that cover full deployment life-cycle for ADF

Any ideas or questions? Leave it here:

<https://github.com/SQLPlayer/azure.datafactory.tools/issues>

# PowerShell module: azure.datafactory.tools

- Fully written in PowerShell, compatible with 5.1
- Uses Microsoft's PS module (Az.DataFactory) for management of ADF objects
- Available in [PowerShell gallery](#)
- **Publish-AdfV2FromJson** function - capabilities:
  - Creation of Azure Data Factory, if not exist (option)
  - Deployment of all type of objects: pipelines, datasets, linked services, data flows & power query, triggers, integration runtimes
  - Copes with dependencies (multiple levels) between objects when deploying (no more worrying about object names)
  - Build-in mechanism to replace the properties with the indicated values (CSV file)
  - Stop/start triggers (option)
  - Dropping objects when not exist in the source (code) (option)
  - Selective deployment: Filtering (include or exclude) objects to be deployed by name and/or type
  - Publish options allow you to control:
    - Whether stop and restarting triggers
    - Whether delete or not objects not in the source
    - Whether create or not a new instance of ADF if it not exist
- Free & Open-Source

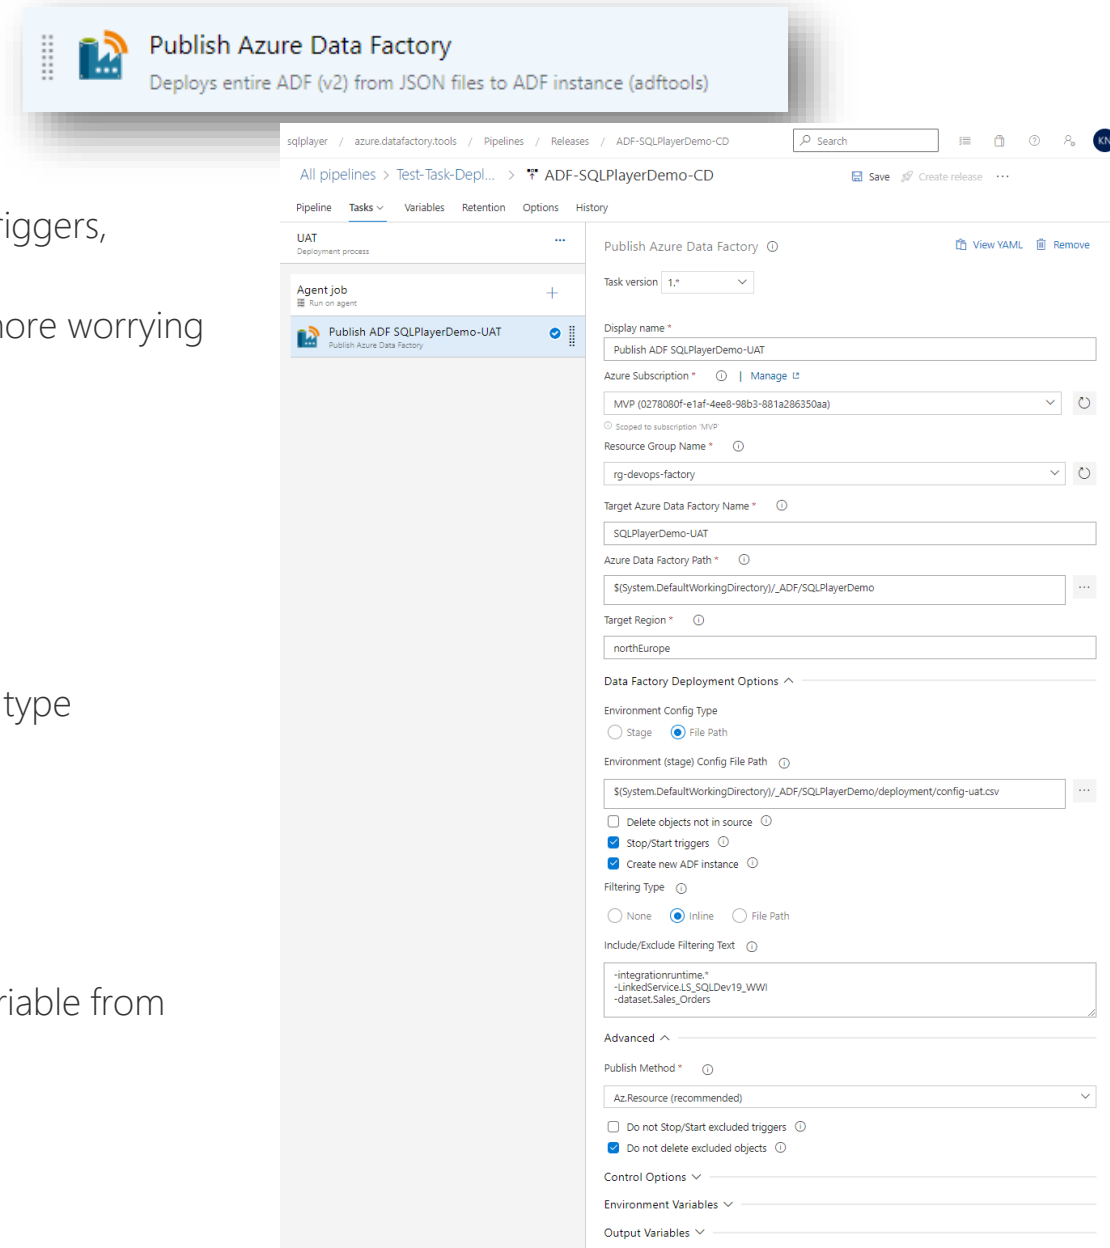

# Task in Azure DevOps: Publish ADF (CD)

## Key capabilities:

- Creation of Azure Data Factory, if not exist (option)
- Deployment of all type of objects: pipelines, datasets, linked services, data flows, triggers, integration runtimes
- Copes with dependencies (multiple levels) between objects when deploying (no more worrying about object names)
- Build-in mechanism to replace the properties with the indicated values (CSV file)
- Update, add or remove any property of ADF artefact
- Selective deployment declared in-line or by pointed file
- Stop/start triggers (option)
- Dropping objects when not exist in the source (code) (option)
- Filtering (include or exclude) objects to be deployed by name and/or type and/or type
- Filtering supports wildcards
- Publish options allow you to control:
  - Whether stop and restarting triggers
  - Whether delete or not objects not in the source
  - Whether create or not a new instance of ADF if it not exist
- Tokenisation in config file allows replace any value by Environment Variable or Variable from DevOps Pipeline
- Global Parameters

# Selective deployment with PowerShell module

You can select objects by objects types & name using include or exclude option.

Allows to select the objects by belonging to a folder (picture)

Name can be **wildcarded**, so all such variants are possible:

```
trigger.*  
dataset.DS_*  
*.PL_*  
linkedService.???KeyVault*  
pipeline.ScdType[123]  
*.*@testFolder
```

▲ Pipelines	5
▶ AzureTable	1
▲ Copy	2
□ PL_CopyMovies	
□ PL_CopyMovies_with_param	
▶ JSON	1
▶ Stackoverflow	1
▲ Datasets	21
▶ ADF	2
▶ AdventureWorks	2
▲ Copy	2
▢ DS_Dst_MovieCsvZip	
▢ DS_Src_MovieCsv	

# Selective deployment in Azure DevOps

😊 In Azure DevOps Task – the list can be provided either as (inline) **text** or from **file** in repo.

To simplify user experience – only one field is exposed in order to define include/exclude rules.

Therefore, an extra character should be provided before the name/pattern:

- + (plus) – for objects you want to include to a deployment
- (minus) - for objects you want to exclude from a deployment

If char is not provided – an inclusion rule would be applied.

A screenshot of the Azure DevOps task configuration interface. It shows a 'Filtering Type' section with three radio buttons: 'None', 'Inline' (which is selected), and 'File Path'. Below this is an 'Include/Exclude Filtering Text' section with a text input field containing the following text:

```
-integrationruntime.*  
-LinkService.LS_SQLDev19_WWI  
-dataset.Sales_Orders
```

# DEMO #3

# Deployment with Azure DevOps

# PowerShell module: Parameters for Stages

How are parameters passed into the deployment? Config CSV File:

```
1 type,name,path,value
2 linkedService,LS_AzureKeyVault,typeProperties.baseUrl,"https://kv-blog-uat.vault.azure.net/"
3 # This is comment - the line will be omitted
4 linkedService,LS_BlobSqlPlayer,typeProperties.connectionString,"DefaultEndpointsProtocol=https;AccountName=sqlplayer;AccountKey=;EndpointSuffix=core.windows.net;"
5 pipeline,PL_CopyMovies,activities[0].outputs[0].parameters.BlobContainer,UAT
6 pipeline,PL_CopyMovies_with_param,parameters.DstBlobContainer.defaultValue,"${$Env:Environment}"
7 pipeline,PL_Wait_Dynamic,parameters.WaitInSec,"{'type': 'int32','defaultValue': 22}"
8 # MINUS means the desired action is to REMOVE encryptedCredential:
9 linkedService,BlobSampleData,-typeProperties.encryptedCredential,
10 # PLUS means the desired action is to ADD new property with associated value:
11 linkedService,BlobSampleData,+typeProperties.accountKey,"${$Env:VARIABLE}"
```

## Option 1 (NEW! and supported now):

Any variables can come from DevOps Pipeline, either normal as well as sensitive values.

To apply replacement for secret values:

Environment Variables must be mapped (Microsoft recommendation).

### Environment Variables ^

Name	Value
SecretFromAKV	\$(SecretFromAKV)

## Option 2:

Another option would be reading secrets directly from provided Azure Key Vault.

Therefore, "Replacement" task is still recommended here as an alternative as for now.

**Azure Key Vault: kv-sqlplayer**  
Azure Key Vault  
**Replace tokens in**  
Replace Tokens

# New task in Azure DevOps: Build ADF (CI)

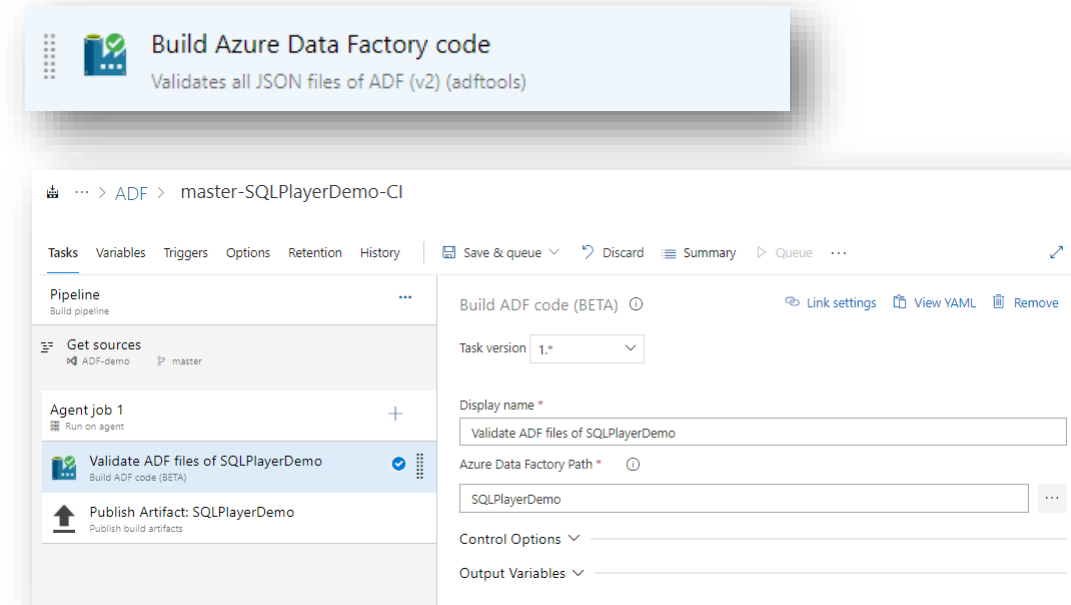

The task has 2 modes:

- **Build only**

- Reads all files and validates its json format
- Checks whether all dependant objects exist
- Checks whether file name equals object name

- **Validate & Export ARM Template**

- uses [ADFUtilities NPM package](#) provided by Microsoft
- Counterpart of **Validate all** and **Export ARM Template** in ADF UI

# New task in Azure DevOps: Test Connection

- Run „Test connection” for a Linked Service
- Smoke tests of (some) Linked Services
- In preview
